Course Project Idea: VisaPath — Multi-Agent Immigration Assistant

Description

VisaPath is an idea for a multi-agent AI system that would answer specific visa/immigration questions grounded in scraped official government data rather than an LLM's general training knowledge. Separate agents would handle retrieval, situation interpretation, and answer composition/verification — aiming to solve a real problem: generic chatbots often give outdated or hallucinated immigration guidance on high-stakes questions.

What I Hope to Learn / Deliverables

I want to build real skill in multi-agent orchestration — decomposing a task across agents with distinct roles, and keeping the system grounded rather than just chaining prompts. Deliverables: a working multi-agent system answering visa questions from current scraped data, architecture documentation, and an accuracy/groundedness evaluation against test questions.

Prior Experience

So far I only have the idea and have started thinking through how to approach it — I haven't built anything yet. I have prior experience with the underlying pieces (APIs, LLM-based systems, and working with structured/scraped data), so I'm not starting from zero on the technical side. What's new for me is the multi-agent dimension specifically: designing distinct agent roles, how they communicate, and how the system stays grounded in real data rather than model guesses. This course gives me the structured space to actually build that out.

Customer / Value / Requirements

- **Customer:** People navigating visa processes who need fast, trustworthy answers.
- **Value:** Reliable answers grounded in verifiable government sources, not model guesses.
- **Requirements:** Answers must be grounded in current scraped data, cover a defined set of specific question types, and be demonstrable end-to-end.
